                Russian Dolls Bandwidth Constraints Model for
                   Diffserv-aware MPLS Traffic Engineering

Status of This Memo

   This memo defines an Experimental Protocol for the Internet
   community. It does not specify an Internet standard of any kind.
   Discussion and suggestions for improvement are requested.
   Distribution of this memo is unlimited.

Abstract

   This document provides specifications for one Bandwidth Constraints
   Model for Diffserv-aware MPLS Traffic Engineering, which is referred
   to as the Russian Dolls Model.

Table of Contents

1. Introduction

   [DSTE-REQ] presents the Service Providers requirements for support of
   Diffserv-aware MPLS Traffic Engineering (DS-TE). This includes the
   fundamental requirement to be able to enforce different Bandwidth
   Constraints for different classes of traffic.

   [DSTE-REQ] also defines the concept of Bandwidth Constraints Model
   for DS-TE and states that "The DS-TE technical solution MUST specify
   at least one Bandwidth Constraints Model and MAY specify multiple
   Bandwidth Constraints Models".

   This document provides a detailed description of one particular
   Bandwidth Constraints Model for DS-TE which is introduced in
   [DSTE-REQ] and called the Russian Dolls Model (RDM).

   [DSTE-PROTO] specifies the Interior Gateway Protocol (IGP) and RSVP-
   TE signaling extensions for support of DS-TE. These extensions
   support RDM.

1.1. Specification of Requirements

   The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
   "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this
   document are to be interpreted as described in [RFC2119].

2. Contributing Authors

   This document was the collective work of several authors. The text
   and content were contributed by the editor and the co-authors listed
   below. (The contact information for the editor appears in the
   Editor's Address section.)

3. Definitions

   For readability a number of definitions from [DSTE-REQ] are repeated
   here:

   Class-Type (CT): the set of Traffic Trunks crossing a link that is
                    governed by a specific set of bandwidth constraints.
                    CT is used for the purposes of link bandwidth
                    allocation, constraint-based routing and admission
                    control. A given Traffic Trunk belongs to the same
                    CT on all links.

   TE-Class: A pair of:

                    i. a Class-Type

                    ii. a preemption priority allowed for that Class-
                    Type. This means that an LSP transporting a Traffic
                    Trunk from that Class-Type can use that preemption
                    priority as the setup priority, the holding
                    priority, or both.

   A number of recovery mechanisms under investigation or specification
   in the IETF take advantage of the concept of bandwidth sharing across
   particular sets of LSPs. "Shared Mesh Restoration" in [GMPLS-RECOV]
   and "Facility-based Computation Model" in [MPLS-BACKUP] are example
   mechanisms that increase bandwidth efficiency by sharing bandwidth
   across backup LSPs protecting against independent failures. To
   ensure that the notion of "Reserved (CTc)" introduced in [DSTE-REQ]
   is compatible with such a concept of bandwidth sharing across
   multiple LSPs, the wording of the "Reserved (CTc)" definition
   provided in [DSTE-REQ] is generalized into the following:

   Reserved (CTc): For a given Class-Type CTc (0 <= c <= MaxCT), let
                    us define "Reserved(CTc)" as the total amount of the
                    bandwidth reserved by all the established LSPs which
                    belong to CTc.

   With this generalization, the Russian Dolls Model definition provided
   in this document is compatible with Shared Mesh Restoration defined
   in [GMPLS-RECOV], so that DS-TE and Shared Mesh Protection can
   operate simultaneously. This assumes that Shared Mesh Restoration
   operates independently within each DS-TE Class-Type and does not
   operate across Class-Types (for example, backup LSPs protecting
   Primary LSPs of CTx also need to belong to CTx; Excess Traffic LSPs
   sharing bandwidth with Backup LSPs of CTx also need to belong to
   CTx).

We also introduce the following definition:

Reserved(CTb,q): Let us define "Reserved(CTb,q)" as the total amount
                  of the bandwidth reserved by all the established
                  LSPs that belong to CTb and have a holding priority
                  of q. Note that if q and CTb do not form one of the
                  8 possible configured TE-Classes, then there cannot
                  be any established LSPs that belongs to CTb and has
                  a holding priority of q; therefore, in this case,
                  Reserved(CTb,q) = 0.

4. Russian Dolls Model Definition

    RDM is defined in the following manner:

        o Maximum Number of Bandwidth Constraints (MaxBC)=
            Maximum Number of Class-Types (MaxCT) = 8

        o for each value of b in the range 0 <= b <= (MaxCT - 1):
            SUM (Reserved (CTc)) <= BCb,
            where the SUM is across all values of c in the
            range b <= c <= (MaxCT - 1)

        o BC0= Maximum Reservable Bandwidth, so that
            SUM (Reserved(CTc)) <= Max-Reservable-Bw,
            where the SUM is across all values of c in the
            range 0 <= c <= (MaxCT - 1)
    A DS-TE LSR implementing RDM MUST support enforcement of Bandwidth
    Constraints in compliance with this definition.

    Both preemption within a CT and across CTs is allowed.

    Where 8 CTs are active, the RDM Bandwidth Constraints can also be
    expressed in the following way:

      - All LSPs from CT7 use no more than BC7

      - All LSPs from CT6 and CT7 use no more than BC6

      - All LSPs from CT5, CT6 and CT7 use no more than BC5

      - etc.

      - All LSPs from CT0, CT1, ..., CT7 use no more than BC0 = "Maximum
        Reservable Bandwidth"

   Purely for illustration purposes, the diagram below represents the
   Russian Dolls Bandwidth Constraints Model in a pictorial manner when
   3 Class-Types are active:

```
   I------------------------------------------------------I
   I-----------------------------I                        I
   I--------------I              I                        I
   I   CT2        I    CT2+CT1   I      CT2+CT1+CT0        I
   I--------------I              I                        I
   I-----------------------------I                        I
   I------------------------------------------------------I

   I-----BC2------>
   I--------------------BC1------>
   I-------------------------BC0=Max Reservable Bw--->
```

   While simpler Bandwidth Constraints models or, conversely, more
   flexible/sophisticated Bandwidth Constraints models can be defined,
   the Russian Dolls Model is attractive in some DS-TE environments for
   the following reasons:

      - Although it is a little less intuitive than the Maximum
        Allocation Model (see [DSTE-MAM]), RDM is still a simple model
        to conceptualize.

      - RDM can be used simultaneously to ensure bandwidth efficiency
        and to protect against QoS degradation of all CTs, whether
        preemption is used or not.

      - RDM can be used in conjunction with preemption to simultaneously
        achieve (i) isolation across CTs (so that each CT is guaranteed
        its share of bandwidth no matter the level of contention by
        other classes), (ii) bandwidth efficiency, and (iii) protection
        against QoS degradation of all CTs.

      - RDM only requires limited protocol extensions such as the ones
        defined in [DSTE-PROTO].

   RDM may not be attractive in some DS-TE environments for the
   following reasons:

      - if the usage of preemption is precluded for some administrative
        reason, while RDM can still ensure bandwidth efficiency and
        protection against QoS degradation of all CTs, RDM cannot
        guarantee isolation across Class-Types.

   Additional considerations on the properties of RDM can be found in
   [BC-CONS] and [BC-MODEL].

As a simple example usage of the "Russian Dolls" Bandwidth
Constraints Model, a network administrator, using one CT for Voice
(CT1) and one CT for data (CT0), might configure on a given link:

   - BC0 = Max-Reservable - Bw = 2.5 Gb/s (i.e., Voice + Data is
     limited to 2.5 Gb/s)

   - BC1 = 1.5 Gb/s (i.e., Voice is limited to 1.5 Gb/s).

5. Example Formulas for Computing "Unreserved TE-Class [i]" with
    Russian Dolls Model

   As specified in [DSTE-PROTO], formulas for computing "Unreserved TE-
   Class [i]" MUST reflect all of the Bandwidth Constraints relevant to
   the CT associated with TE-Class[i], and thus, depend on the Bandwidth
   Constraints Model. Thus, a DS-TE LSR implementing RDM MUST reflect
   the RDM Bandwidth Constraints defined in section 4 above when
   computing "Unreserved TE-Class [i]".

   As explained in [DSTE-PROTO], the details of admission control
   algorithms, as well as formulas for computing "Unreserved TE-Class
   [i]", are outside the scope of the IETF work. Keeping that in mind,
   we provide in this section an example for illustration purposes, of
   how values for the unreserved bandwidth for TE-Class[i] might be
   computed with RDM. In the example, we assume the basic admission
   control algorithm, which simply deducts the exact bandwidth of any
   established LSP from all of the Bandwidth Constraints relevant to the
   CT associated with that LSP.

   We assume that:

       TE-Class [i] <--> < CTc , preemption p>

   in the configured TE-Class mapping.

   For readability, formulas are first shown assuming only 3 CTs are
   active. The formulas are then extended to cover the cases where more
   CTs are used.

   If CTc = CT0, then "Unreserved TE-Class [i]" =
      [BC0 - SUM (Reserved(CTb,q))] for q <= p and 0 <= b <= 2

   If CTc = CT1, then "Unreserved TE-Class [i]" =
      MIN [
      [BC1 - SUM (Reserved(CTb,q))] for q <= p and 1 <= b <= 2,
      [BC0 - SUM (Reserved(CTb,q))] for q <= p and 0 <= b <= 2
            ]

```
If CTc = CT2, then "Unreserved TE-Class [i]" =
   MIN  [
   [ BC2 - SUM ( Reserved(CTb,q) ) ] for q <= p and 2 <= b <= 2,
   [ BC1 - SUM ( Reserved(CTb,q) ) ] for q <= p and 1 <= b <= 2,
   [ BC0 - SUM ( Reserved(CTb,q) ) ] for q <= p and 0 <= b <= 2
         ]
```

The formula can be generalized to 8 active CTs and expressed in a more compact way in the following:

```
 "Unreserved TE-Class [i]" =
   MIN  [
[ BCc - SUM ( Reserved(CTb,q) ) ] for q <= p and c <= b <= 7,
[ BC(c-1) - SUM ( Reserved(CTb,q) ) ] for q <= p and (c-1)<= b <= 7,
    . . .
[ BC0 - SUM ( Reserved(CTb,q) ) ] for q <= p and 0 <= b <= 7,
         ]
```

   where:

      TE-Class [i] <--> < CTc , preemption p>
      in the configured TE-Class mapping.

6. Receiving Both Maximum Reservable Bandwidth and Bandwidth
    Constraints sub-TLVs

    [DSTE-PROTO] states that "A DS-TE LSR, which does advertise BCs, MUST
    use the new "Bandwidth Constraints" sub-TLV (in addition to the
    existing Maximum Reservable Bandwidth sub-TLV) to do so."

    With RDM, BC0 is equal to the Maximum Reservable Bandwidth because
    they both represent the aggregate constraint across all CTs. Thus, a
    DS-TE LSR, receiving both the "Maximum Reservable Bw" sub-TLV and the
    new "Bandwidth Constraints" sub-TLV (which contains BC0) for a given
    link where the RDM model is used, MAY ignore the "Maximum Reservable
    Bw" sub-TLV.

7. Security Considerations

    Security considerations related to the use of DS-TE are discussed in
    [DSTE-PROTO]. Those apply independently of the Bandwidth Constraints
    Model, including RDM specified in this document.

8. IANA Considerations

    [DSTE-PROTO] defines a new name space for "Bandwidth Constraints
    Model Id". The guidelines for allocation of values in that name
    space are detailed in section 13.1 of [DSTE-PROTO]. In accordance

with these guidelines, the IANA has assigned a Bandwidth Constraints
Model Id for RDM from the range 0-239 (which is to be managed as per
the "Specification Required" policy defined in [IANA-CONS]).

Bandwidth Constraints Model Id 0 was allocated by IANA to RDM.

9. Acknowledgements

We thank Martin Tatham for his key contribution in this work.
Tatiana Renko is also warmly thanked for her instantiation of the
Russian Doll.

Appendix A: Addressing [DSTE-REQ] Scenarios

   This appendix provides examples of how the Russian Dolls Bandwidth
   Constraints Model can be used to support each of the scenarios
   described in [DSTE-REQ].

A.1.   Scenario 1: Limiting Amount of Voice

   By configuring on every link:

      - Bandwidth Constraint 1 (for CT1 = Voice) = "certain percentage"
        of link capacity

      - BC0 (for CT1=Voice + CT0=Data) = link capacity

   By configuring:

      - every CT1/Voice TE-LSP with preemption = 0

      - every CT0/Data TE-LSP with preemption = 1

   DS-TE with the Russian Dolls Model will address all the requirements:

      - amount of Voice traffic limited to desired percentage on every
        link

      - data traffic capable of using all remaining link capacity

      - voice traffic capable of preempting other traffic

A.2.   Scenario 2: Maintain Relative Proportion of Traffic Classes

   By configuring on every link:

      - BC2 (for CT2) = e.g., 45%

      - BC1 (for CT1+CT2) = e.g., 80%

      - BC0 (for CT0+CT1+CT2) = e.g., 100%

   DS-TE with the RDM will ensure that the amount of traffic of each CT
   established on a link is within acceptable levels as compared to the
   resources allocated to the corresponding Diffserv Per Hop Behaviors
   (PHBs) regardless of which order the LSPs are routed in, regardless
   of which preemption priorities are used by which LSPs and regardless
   of failure situations.

By also configuring:

    - every CT2/Voice TE-LSP with preemption = 0

    - every CT1/Premium Data TE-LSP with preemption = 1

    - every CT0/Best-Effort TE-LSP with preemption = 2

DS-TE with the Russian Dolls Model will also ensure that:

    - CT2 Voice LSPs always have first preemption priority in order to
      use the CT2 capacity

    - CT1 Premium Data LSPs always have second preemption priority in
      order to use the CT1 capacity

    - Best-Effort can use up to link capacity of what is left by CT2
      and CT1.

Optional automatic adjustment of Diffserv scheduling configuration
could be used for maintaining very strict relationships between the
amounts of established traffic of each Class Type and corresponding
Diffserv resources.

A.3. Scenario 3: Guaranteed Bandwidth Services

By configuring on every link:

    - BC1 (for CT1) = "given" percentage of link bandwidth
      (appropriate to achieve the Guaranteed Bandwidth service's QoS
      objectives)

    - BC0 (for CT0+CT1) = 100% of link bandwidth

DS-TE with the Russian Dolls Model will ensure that the amount of
Guaranteed Bandwidth Traffic established on every link remains below
the given percentage so that it will always meet its QoS objectives.
At the same time, it will allow traffic engineering of the rest of
the traffic such that links can be filled up.
