Abstract

The United States of America has adopted a suite of Secure Hash Algorithms (SHAs), including four beyond SHA-1, as part of a Federal Information Processing Standard (FIPS), specifically SHA-224 (RFC 3874), SHA-256, SHA-384, and SHA-512. The purpose of this document is to make source code performing these hash functions conveniently available to the Internet community. The sample code supports input strings of arbitrary bit length. SHA-1's sample code from RFC 3174 has also been updated to handle input strings of arbitrary bit length. Most of the text herein was adapted by the authors from FIPS 180-2.

Code to perform SHA-based HMACs, with arbitrary bit length text, is also included.

1. Overview of Contents

NOTE: Much of the text below is taken from [FIPS180-2] and assertions therein of the security of the algorithms described are made by the US Government, the author of [FIPS180-2], and not by the authors of this document.

The text below specifies Secure Hash Algorithms, SHA-224 [RFC3874], SHA-256, SHA-384, and SHA-512, for computing a condensed representation of a message or a data file. (SHA-1 is specified in [RFC3174].) When a message of any length < 2^64 bits (for SHA-224 and SHA-256) or < 2^128 bits (for SHA-384 and SHA-512) is input to one of these algorithms, the result is an output called a message digest. The message digests range in length from 224 to 512 bits, depending on the algorithm. Secure hash algorithms are typically used with other cryptographic algorithms, such as digital signature algorithms and keyed hash authentication codes, or in the generation of random numbers [RFC4086].

The four algorithms specified in this document are called secure because it is computationally infeasible to (1) find a message that corresponds to a given message digest, or (2) find two different messages that produce the same message digest. Any change to a message in transit will, with very high probability, result in a different message digest. This will result in a verification failure when the secure hash algorithm is used with a digital signature algorithm or a keyed-hash message authentication algorithm.

The code provided herein supports input strings of arbitrary bit length. SHA-1's sample code from [RFC3174] has also been updated to handle input strings of arbitrary bit length. See Section 1.1 for license information for this code.

Section 2 below defines the terminology and functions used as building blocks to form these algorithms. Section 3 describes the fundamental operations on words from which these algorithms are built. Section 4 describes how messages are padded up to an integral multiple of the required block size and then parsed into blocks. Section 5 defines the constants and the composite functions used to specify these algorithms. Section 6 gives the actual specification for the SHA-224, SHA-256, SHA-384, and SHA-512 functions. Section 7 provides pointers to the specification of HMAC keyed message authentication codes based on the SHA algorithms. Section 8 gives sample code for the SHA algorithms and Section 9 code for SHA-based HMACs. The SHA-based HMACs will accept arbitrary bit length text.

1.1. License

Permission is granted for all uses, commercial and non-commercial, of the sample code found in Section 8. Royalty free license to use, copy, modify and distribute the software found in Section 8 is granted, provided that this document is identified in all material mentioning or referencing this software, and provided that redistributed derivative works do not contain misleading author or version information.

The authors make no representations concerning either the merchantability of this software or the suitability of this software for any particular purpose. It is provided "as is" without express or implied warranty of any kind.

2. Notation for Bit Strings and Integers

The following terminology related to bit strings and integers will be used:

a. A hex digit is an element of the set {0, 1, ... , 9, A, ... , F}. A hex digit is the representation of a 4-bit string. Examples: 7 = 0111, A = 1010.

b. A word equals a 32-bit or 64-bit string, which may be represented as a sequence of 8 or 16 hex digits, respectively. To convert a word to hex digits, each 4-bit string is converted to its hex equivalent as described in (a) above. Example:

   1010 0001 0000 0011 1111 1110 0010 0011 = A103FE23.

   Throughout this document, the "big-endian" convention is used when expressing both 32-bit and 64-bit words, so that within each word the most significant bit is shown in the left-most bit position.

c. An integer may be represented as a word or pair of words.

   An integer between 0 and 2^32 - 1 inclusive may be represented as a 32-bit word. The least significant four bits of the integer are represented by the right-most hex digit of the word representation. Example: the integer 291 = 2^8+2^5+2^1+2^0 = 256+32+2+1 is represented by the hex word 00000123.

   The same holds true for an integer between 0 and 2^64-1 inclusive, which may be represented as a 64-bit word.

If Z is an integer, 0 <= z < 2^64, then z = (2^32)x + y where 0 <= x < 2^32 and 0 <= y < 2^32. Since x and y can be represented as words X and Y, respectively, z can be represented as the pair of words (X,Y).

d. block = 512-bit or 1024-bit string. A block (e.g., B) may be represented as a sequence of 32-bit or 64-bit words.

3. Operations on Words

The following logical operators will be applied to words in all four hash operations specified herein. SHA-224 and SHA-256 operate on 32-bit words, while SHA-384 and SHA-512 operate on 64-bit words.

In the operations below, x<<n is obtained as follows: discard the left-most n bits of x and then pad the result with n zeroed bits on the right (the result will still be the same number of bits).

a. Bitwise logical word operations

X AND Y = bitwise logical "and" of X and Y.

X OR Y = bitwise logical "inclusive-or" of X and Y.

X XOR Y = bitwise logical "exclusive-or" of X and Y.

NOT X = bitwise logical "complement" of X.

Example:

```
         01101100101110011101001001111011
   XOR   01100101110000010110100110110111
         --------------------------------
     =   00001001011110001011101111001100
```

b. The operation X + Y is defined as follows: words X and Y represent w-bit integers x and y, where 0 <= x < 2^w and 0 <= y < 2^w. For positive integers n and m, let

n mod m

be the remainder upon dividing n by m. Compute

z = (x + y) mod 2^w.

Then 0 <= z < 2^w. Convert z to a word, Z, and define Z = X + Y.

c. The right shift operation SHR^n(x), where x is a w-bit word and n is an integer with 0 <= n < w, is defined by

```
SHR^n(x) = x>>n
```

d. The rotate right (circular right shift) operation ROTR^n(x), where x is a w-bit word and n is an integer with 0 <= n < w, is defined by

```
ROTR^n(x) = (x>>n) OR (x<<(w-n))
```

e. The rotate left (circular left shift) operation ROTL^n(x), where x is a w-bit word and n is an integer with 0 <= n < w, is defined by

```
ROTL^n(X)  =  (x<<n) OR (x>>w-n)
```

Note the following equivalence relationships, where w is fixed in each relationship:

```
ROTL^n(x) = ROTR^(w-x)(x)

ROTR^n(x) = ROTL^(w-n)(x)
```

4. Message Padding and Parsing

The hash functions specified herein are used to compute a message digest for a message or data file that is provided as input. The message or data file should be considered to be a bit string. The length of the message is the number of bits in the message (the empty message has length 0). If the number of bits in a message is a multiple of 8, for compactness we can represent the message in hex. The purpose of message padding is to make the total length of a padded message a multiple of 512 for SHA-224 and SHA-256 or a multiple of 1024 for SHA-384 and SHA-512.

The following specifies how this padding shall be performed. As a summary, a "1" followed by a number of "0"s followed by a 64-bit or 128-bit integer are appended to the end of the message to produce a padded message of length 512*n or 1024*n. The minimum number of "0"s necessary to meet this criterion is used. The appended integer is the length of the original message. The padded message is then processed by the hash function as n 512-bit or 1024-bit blocks.

4.1. SHA-224 and SHA-256

Suppose a message has length L < 2^64. Before it is input to the hash function, the message is padded on the right as follows:

a. "1" is appended. Example: if the original message is "01010000", this is padded to "010100001".

b. K "0"s are appended where K is the smallest, non-negative solution to the equation

```
L + 1 + K = 448 (mod 512)
```

c. Then append the 64-bit block that is L in binary representation. After appending this block, the length of the message will be a multiple of 512 bits.

Example: Suppose the original message is the bit string

```
01100001 01100010 01100011 01100100 01100101
```

After step (a), this gives

```
01100001 01100010 01100011 01100100 01100101 1
```

Since L = 40, the number of bits in the above is 41 and K = 407 "0"s are appended, making the total now 448. This gives the following in hex:

```
61626364 65800000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000
```

The 64-bit representation of L = 40 is hex 00000000 00000028. Hence the final padded message is the following hex:

```
61626364 65800000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000028
```

4.2. SHA-384 and SHA-512

Suppose a message has length L < 2^128. Before it is input to the hash function, the message is padded on the right as follows:

a. "1" is appended. Example: if the original message is "01010000", this is padded to "010100001".

b. K "0"s are appended where K is the smallest, non-negative solution to the equation

```
L + 1 + K = 896 (mod 1024)
```

c. Then append the 128-bit block that is L in binary representation. After appending this block, the length of the message will be a multiple of 1024 bits.

Example: Suppose the original message is the bit string

```
01100001 01100010 01100011 01100100 01100101
```

After step (a) this gives

```
01100001 01100010 01100011 01100100 01100101 1
```

Since L = 40, the number of bits in the above is 41 and K = 855 "0"s are appended, making the total now 896. This gives the following in hex:

```
61626364 65800000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
```

The 128-bit representation of L = 40 is hex 00000000 00000000 00000000 00000028. Hence the final padded message is the following hex:

```
61626364 65800000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
```

```
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000028
```

5. Functions and Constants Used

The following subsections give the six logical functions and the table of constants used in each of the hash functions.

5.1. SHA-224 and SHA-256

SHA-224 and SHA-256 use six logical functions, where each function operates on 32-bit words, which are represented as x, y, and z. The result of each function is a new 32-bit word.

```
CH( x, y, z) = (x AND y) XOR ( (NOT x) AND z)

MAJ( x, y, z) = (x AND y) XOR (x AND z) XOR (y AND z)

BSIG0(x) = ROTR^2(x) XOR ROTR^13(x) XOR ROTR^22(x)

BSIG1(x) = ROTR^6(x) XOR ROTR^11(x) XOR ROTR^25(x)

SSIG0(x) = ROTR^7(x) XOR ROTR^18(x) XOR SHR^3(x)

SSIG1(x) = ROTR^17(x) XOR ROTR^19(x) XOR SHR^10(x)
```

SHA-224 and SHA-256 use the same sequence of sixty-four constant 32-bit words, K0, K1, ..., K63. These words represent the first thirty-two bits of the fractional parts of the cube roots of the first sixty-four prime numbers. In hex, these constant words are as follows (from left to right):

```
428a2f98 71374491 b5c0fbcf e9b5dba5
3956c25b 59f111f1 923f82a4 ab1c5ed5

90befffa a4506ceb bef9a3f7 c67178f2
```

5.2. SHA-384 and SHA-512

SHA-384 and SHA-512 each use six logical functions, where each function operates on 64-bit words, which are represented as x, y, and z. The result of each function is a new 64-bit word.

```
CH( x, y, z) = (x AND y) XOR ( (NOT x) AND z)

MAJ( x, y, z) = (x AND y) XOR (x AND z) XOR (y AND z)

BSIG0(x) = ROTR^28(x) XOR ROTR^34(x) XOR ROTR^39(x)

BSIG1(x) = ROTR^14(x) XOR ROTR^18(x) XOR ROTR^41(x)

SSIG0(x) = ROTR^1(x) XOR ROTR^8(x) XOR SHR^7(x)

SSIG1(x) = ROTR^19(x) XOR ROTR^61(x) XOR SHR^6(x)
```

SHA-384 and SHA-512 use the same sequence of eighty constant 64-bit words, K0, K1, ... K79. These words represent the first sixty-four bits of the fractional parts of the cube roots of the first eighty prime numbers. In hex, these constant words are as follows (from left to right):

```
428a2f98d728ae22 7137449123ef65cd b5c0fbcfec4d3b2f e9b5dba58189dbbc

6. Computing the Message Digest

The output of each of the secure hash functions, after being applied to a message of N blocks, is the hash quantity H(N). For SHA-224 and SHA-256, H(i) can be considered to be eight 32-bit words, H(i)0, H(i)1, ... H(i)7. For SHA-384 and SHA-512, it can be considered to be eight 64-bit words, H(i)0, H(i)1, ..., H(i)7.

As described below, the hash words are initialized, modified as each message block is processed, and finally concatenated after processing the last block to yield the output. For SHA-256 and SHA-512, all of the H(N) variables are concatenated while the SHA-224 and SHA-384 hashes are produced by omitting some from the final concatenation.

6.1. SHA-224 and SHA-256 Initialization

For SHA-224, the initial hash value, H(0), consists of the following 32-bit words in hex:

```
H(0)0 = c1059ed8
H(0)1 = 367cd507
H(0)2 = 3070dd17
H(0)3 = f70e5939
H(0)4 = ffc00b31
H(0)5 = 68581511
H(0)6 = 64f98fa7
H(0)7 = befa4fa4
```

For SHA-256, the initial hash value, H(0), consists of the following eight 32-bit words, in hex. These words were obtained by taking the first thirty-two bits of the fractional parts of the square roots of the first eight prime numbers.

```
H(0)0 = 6a09e667
H(0)1 = bb67ae85
H(0)2 = 3c6ef372
H(0)3 = a54ff53a
H(0)4 = 510e527f
H(0)5 = 9b05688c
H(0)6 = 1f83d9ab
H(0)7 = 5be0cd19
```

6.2. SHA-224 and SHA-256 Processing

SHA-224 and SHA-256 perform identical processing on messages blocks and differ only in how H(0) is initialized and how they produce their final output. They may be used to hash a message, M, having a length of L bits, where 0 <= L < 2^64. The algorithm uses (1) a message

schedule of sixty-four 32-bit words, (2) eight working variables of 32 bits each, and (3) a hash value of eight 32-bit words.

The words of the message schedule are labeled W0, W1, ..., W63. The eight working variables are labeled a, b, c, d, e, f, g, and h. The words of the hash value are labeled H(i)0, H(i)1, ..., H(i)7, which will hold the initial hash value, H(0), replaced by each successive intermediate hash value (after each message block is processed), H(i), and ending with the final hash value, H(N), after all N blocks are processed. They also use two temporary words, T1 and T2.

The input message is padded as described in Section 4.1 above then parsed into 512-bit blocks, which are considered to be composed of 16 32-bit words M(i)0, M(i)1, ..., M(i)15. The following computations are then performed for each of the N message blocks. All addition is performed modulo 2^32.

```
For i = 1 to N

   1. Prepare the message schedule W:
      For t = 0 to 15
         Wt = M(i)t
      For t = 16 to 63
         Wt = SSIG1(W(t-2)) + W(t-7) + SSIG0(t-15) + W(t-16)

   2. Initialize the working variables:
      a = H(i-1)0
      b = H(i-1)1
      c = H(i-1)2
      d = H(i-1)3
      e = H(i-1)4
      f = H(i-1)5
      g = H(i-1)6
      h = H(i-1)7

   3. Perform the main hash computation:
      For t = 0 to 63
         T1 = h + BSIG1(e) + CH(e,f,g) + Kt + Wt
         T2 = BSIG0(a) + MAJ(a,b,c)
         h = g
         g = f
         f = e
         e = d + T1
         d = c
         c = b
         b = a
         a = T1 + T2
```

4. Compute the intermediate hash value H(i):
   H(i)0 = a + H(i-1)0
   H(i)1 = b + H(i-1)1
   H(i)2 = c + H(i-1)2
   H(i)3 = d + H(i-1)3
   H(i)4 = e + H(i-1)4
   H(i)5 = f + H(i-1)5
   H(i)6 = g + H(i-1)6
   H(i)7 = h + H(i-1)7

After the above computations have been sequentially performed for all of the blocks in the message, the final output is calculated. For SHA-256, this is the concatenation of all of H(N)0, H(N)1, through H(N)7. For SHA-224, this is the concatenation of H(N)0, H(N)1, through H(N)6.

6.3. SHA-384 and SHA-512 Initialization

For SHA-384, the initial hash value, H(0), consists of the following eight 64-bit words, in hex. These words were obtained by taking the first sixty-four bits of the fractional parts of the square roots of the ninth through sixteenth prime numbers.

```
H(0)0 = cbbb9d5dc1059ed8
H(0)1 = 629a292a367cd507
H(0)2 = 9159015a3070dd17
H(0)3 = 152fecd8f70e5939
H(0)4 = 67332667ffc00b31
H(0)5 = 8eb44a8768581511
H(0)6 = db0c2e0d64f98fa7
H(0)7 = 47b5481dbefa4fa4
```

For SHA-512, the initial hash value, H(0), consists of the following eight 64-bit words, in hex. These words were obtained by taking the first sixty-four bits of the fractional parts of the square roots of the first eight prime numbers.

```
H(0)0 = 6a09e667f3bcc908
H(0)1 = bb67ae8584caa73b
H(0)2 = 3c6ef372fe94f82b
H(0)3 = a54ff53a5f1d36f1
H(0)4 = 510e527fade682d1
H(0)5 = 9b05688c2b3e6c1f
H(0)6 = 1f83d9abfb41bd6b
H(0)7 = 5be0cd19137e2179
```

6.4. SHA-384 and SHA-512 Processing

SHA-384 and SHA-512 perform identical processing on message blocks and differ only in how H(0) is initialized and how they produce their final output. They may be used to hash a message, M, having a length of L bits, where 0 <= L < 2^128. The algorithm uses (1) a message schedule of eighty 64-bit words, (2) eight working variables of 64 bits each, and (3) a hash value of eight 64-bit words.

The words of the message schedule are labeled W0, W1, ..., W79. The eight working variables are labeled a, b, c, d, e, f, g, and h. The words of the hash value are labeled H(i)0, H(i)1, ..., H(i)7, which will hold the initial hash value, H(0), replaced by each successive intermediate hash value (after each message block is processed), H(i), and ending with the final hash value, H(N) after all N blocks are processed.

The input message is padded as described in Section 4.2 above, then parsed into 1024-bit blocks, which are considered to be composed of 16 64-bit words M(i)0, M(i)1, ..., M(i)15. The following computations are then performed for each of the N message blocks. All addition is performed modulo 2^64.

For i = 1 to N

1. Prepare the message schedule W:

```
For t = 0 to 15
   Wt = M(i)t
For t = 16 to 79
   Wt = SSIG1(W(t-2)) + W(t-7) + SSIG0(t-15) + W(t-16)
```

2. Initialize the working variables:

```
a = H(i-1)0
b = H(i-1)1
c = H(i-1)2
d = H(i-1)3
e = H(i-1)4
f = H(i-1)5
g = H(i-1)6
h = H(i-1)7
```

3. Perform the main hash computation:

```
For t = 0 to 79
   T1 = h + BSIG1(e) + CH(e,f,g) + Kt + Wt
   T2 = BSIG0(a) + MAJ(a,b,c)
   h = g
   g = f
   f = e
```

```
        e = d + T1
        d = c
        c = b
        b = a
        a = T1 + T2
```

4. Compute the intermediate hash value H(i):

```
   H(i)0 = a + H(i-1)0
   H(i)1 = b + H(i-1)1
   H(i)2 = c + H(i-1)2
   H(i)3 = d + H(i-1)3
   H(i)4 = e + H(i-1)4
   H(i)5 = f + H(i-1)5
   H(i)6 = g + H(i-1)6
   H(i)7 = h + H(i-1)7
```

After the above computations have been sequentially performed for all of the blocks in the message, the final output is calculated. For SHA-512, this is the concatenation of all of H(N)0, H(N)1, through H(N)7. For SHA-384, this is the concatenation of H(N)0, H(N)1, through H(N)5.

7. SHA-Based HMACs

HMAC is a method for computing a keyed MAC (message authentication code) using a hash function as described in [RFC2104]. It uses a key to mix in with the input text to produce the final hash.

Sample code is also provided, in Section 8.3 below, to perform HMAC based on any of the SHA algorithms described herein. The sample code found in [RFC2104] was written in terms of a specified text size. Since SHA is defined in terms of an arbitrary number of bits, the sample HMAC code has been written to allow the text input to HMAC to have an arbitrary number of octets and bits. A fixed-length interface is also provided.

8. C Code for SHAs

Below is a demonstration implementation of these secure hash functions in C. Section 8.1 contains the header file sha.h, which declares all constants, structures, and functions used by the sha and hmac functions. Section 8.2 contains the C code for sha1.c, sha224-256.c, sha384-512.c, and usha.c along with sha-private.h, which provides some declarations common to all the sha functions. Section 8.3 contains the C code for the hmac functions. Section 8.4 contains a test driver to exercise the code.

For each of the digest length $$$, there is the following set of constants, a structure, and functions:

```
Constants:
   SHA$$$HashSize      number of octets in the hash
   SHA$$$HashSizeBits  number of bits in the hash
   SHA$$$_Message_Block_Size
                       number of octets used in the intermediate
                       message blocks
   shaSuccess = 0      constant returned by each function on success
   shaNull = 1         constant returned by each function when
                       presented with a null pointer parameter
   shaInputTooLong = 2  constant returned by each function when the
                       input data is too long
   shaStateError       constant returned by each function when
                       SHA$$$Input is called after SHA$$$FinalBits or
                       SHA$$$Result.

Structure:
   typedef SHA$$$Context
                       an opaque structure holding the complete state
                       for producing the hash

Functions:
               int SHA$$$Reset(SHA$$$Context *);
         Reset the hash context state
   int SHA$$$Input(SHA$$$Context *, const uint8_t *octets,
               unsigned int bytecount);
         Incorporate bytecount octets into the hash.
   int SHA$$$FinalBits(SHA$$$Context *, const uint8_t octet,
               unsigned int bitcount);
         Incorporate bitcount bits into the hash.  The bits are in
         the upper portion of the octet.  SHA$$$Input() cannot be
         called after this.
   int SHA$$$Result(SHA$$$Context *,
               uint8_t Message_Digest[SHA$$$HashSize]);
         Do the final calculations on the hash and copy the value
         into Message_Digest.
```

In addition, functions with the prefix USHA are provided that take a SHAversion value (SHA$$$) to select the SHA function suite. They add the following constants, structure, and functions:

```
Constants:
   shaBadParam         constant returned by USHA functions when
                       presented with a bad SHAversion (SHA$$$)
                       parameter
```

```
      SHA$$$              SHAversion enumeration values, used by usha
                          and hmac functions to select the SHA function
                          suite

   Structure:
      typedef USHAContext
                          an opaque structure holding the complete state
                          for producing the hash

   Functions:
      int USHAReset(USHAContext *, SHAversion whichSha);
            Reset the hash context state.
      int USHAInput(USHAContext *,
                  const uint8_t *bytes, unsigned int bytecount);
            Incorporate bytecount octets into the hash.
      int USHAFinalBits(USHAContext *,
                  const uint8_t bits, unsigned int bitcount);
                  Incorporate bitcount bits into the hash.
      int USHAResult(USHAContext *,
                  uint8_t Message_Digest[USHAMaxHashSize]);
            Do the final calculations on the hash and copy the value
            into Message_Digest.  Octets in Message_Digest beyond
      USHAHashSize(whichSha) are left untouched.
                  int USHAHashSize(enum SHAversion whichSha);
            The number of octets in the given hash.
      int USHAHashSizeBits(enum SHAversion whichSha);
            The number of bits in the given hash.
      int USHABlockSize(enum SHAversion whichSha);
            The internal block size for the given hash.

   The hmac functions follow the same pattern to allow any length of
   text input to be used.

   Structure:
      typedef HMACContext an opaque structure holding the complete state
                          for producing the hash

   Functions:
      int hmacReset(HMACContext *ctx, enum SHAversion whichSha,
                  const unsigned char *key, int key_len);
            Reset the hash context state.
      int hmacInput(HMACContext *ctx, const unsigned char *text,
                  int text_len);
            Incorporate text_len octets into the hash.
      int hmacFinalBits(HMACContext *ctx, const uint8_t bits,
                  unsigned int bitcount);
            Incorporate bitcount bits into the hash.
```

```
      int hmacResult(HMACContext *ctx,
                  uint8_t Message_Digest[USHAMaxHashSize]);
            Do the final calculations on the hash and copy the value
            into Message_Digest.  Octets in Message_Digest beyond
            USHAHashSize(whichSha) are left untouched.
```

In addition, a combined interface is provided, similar to that shown in RFC 2104, that allows a fixed-length text input to be used.

```
      int hmac(SHAversion whichSha,
                  const unsigned char *text, int text_len,
                  const unsigned char *key, int key_len,
                  uint8_t Message_Digest[USHAMaxHashSize]);
            Calculate the given digest for the given text and key, and
            return the resulting hash.  Octets in Message_Digest beyond
            USHAHashSize(whichSha) are left untouched.
```

8.1. The .h File

```
/*************************** sha.h ***************************/
/****************** See RFC 4634 for details ******************/
#ifndef _SHA_H_
#define _SHA_H_

8.2. The SHA Code

This code is primarily intended as expository and could be optimized further. For example, the assignment rotations through the variables a, b, ..., h could be treated as a cycle and the loop unrolled, rather than doing the explicit copying.

Note that there are alternative representations of the Ch() and Maj() functions controlled by an ifdef.

8.2.1. sha1.c

```
/*************************** sha1.c ***************************/
/******************** See RFC 4634 for details ******************/
/*
 *  Description:
 *      This file implements the Secure Hash Signature Standard
 *      algorithms as defined in the National Institute of Standards
 *      and Technology Federal Information Processing Standards
 *      Publication (FIPS PUB) 180-1 published on April 17, 1995, 180-2
 *      published on August 1, 2002, and the FIPS PUB 180-2 Change
 *      Notice published on February 28, 2004.
 *
 *      A combined document showing all algorithms is available at
 *              http://csrc.nist.gov/publications/fips/
 *              fips180-2/fips180-2withchangenotice.pdf
 *
 *      The SHA-1 algorithm produces a 160-bit message digest for a
 *      given data stream.  It should take about 2**n steps to find a
 *      message with the same digest as a given message and
 *      2**(n/2) to find any two messages with the same digest,
 *      when n is the digest size in bits.  Therefore, this
 *      algorithm can serve as a means of providing a
 *      "fingerprint" for a message.
 *
 *  Portability Issues:
 *      SHA-1 is defined in terms of 32-bit "words".  This code
 *      uses <stdint.h> (included via "sha.h") to define 32 and 8
 *      bit unsigned integer types.  If your C compiler does not
 *      support 32 bit unsigned integers, this code is not
 *      appropriate.
 *
 *  Caveats:
 *      SHA-1 is designed to work with messages less than 2^64 bits
 *      long. This implementation uses SHA1Input() to hash the bits
 *      that are a multiple of the size of an 8-bit character, and then
 *      uses SHA1FinalBits() to hash the final few bits of the input.
 */

8.2.3. sha384-512.c

```
/************************** sha384-512.c ***************************/
/********************** See RFC 4634 for details ********************/
/*
 * Description:
 *   This file implements the Secure Hash Signature Standard
 *   algorithms as defined in the National Institute of Standards
 *   and Technology Federal Information Processing Standards
 *   Publication (FIPS PUB) 180-1 published on April 17, 1995, 180-2
 *   published on August 1, 2002, and the FIPS PUB 180-2 Change
 *   Notice published on February 28, 2004.
 *
 *   A combined document showing all algorithms is available at
 *       http://csrc.nist.gov/publications/fips/
 *       fips180-2/fips180-2withchangenotice.pdf
 *
 *   The SHA-384 and SHA-512 algorithms produce 384-bit and 512-bit
 *   message digests for a given data stream. It should take about
 *   2**n steps to find a message with the same digest as a given
 *   message and 2**(n/2) to find any two messages with the same
 *   digest, when n is the digest size in bits. Therefore, this
 *   algorithm can serve as a means of providing a
 *   "fingerprint" for a message.
 *
```

```
 * Portability Issues:
 *   SHA-384 and SHA-512 are defined in terms of 64-bit "words",
 *   but if USE_32BIT_ONLY is #defined, this code is implemented in
 *   terms of 32-bit "words". This code uses <stdint.h> (included
 *   via "sha.h") to define the 64, 32 and 8 bit unsigned integer
 *   types. If your C compiler does not support 64 bit unsigned
 *   integers, and you do not #define USE_32BIT_ONLY, this code is
 *   not appropriate.
 *
 * Caveats:
 *   SHA-384 and SHA-512 are designed to work with messages less
 *   than 2^128 bits long. This implementation uses
 *   SHA384/512Input() to hash the bits that are a multiple of the
 *   size of an 8-bit character, and then uses SHA384/256FinalBits()
 *   to hash the final few bits of the input.
 *
 */

#include "sha.h"
#include "sha-private.h"

#ifdef USE_32BIT_ONLY
/*
 * Define 64-bit arithmetic in terms of 32-bit arithmetic.

/*
 * HMACResult
 *
 * Description:
 *   This function will return the N-byte message digest into the
 *   Message_Digest array provided by the caller.
 *   NOTE: The first octet of hash is stored in the 0th element,
 *      the last octet of hash in the Nth element.
 *
 * Parameters:
 *   context: [in/out]
 *     The context to use to calculate the HMAC hash.
 *   digest: [out]
 *     Where the digest is returned.
 *   NOTE 2: The length of the hash is determined by the value of
 *      whichSha that was passed to hmacReset().
 *
 * Returns:
 *   sha Error Code.
 *
 */
int hmacResult(HMACContext *ctx, uint8_t *digest)
{
  if (!ctx) return shaNull;

         /* then results of 1st hash */
         USHAInput(&ctx->shaContext, digest, ctx->hashSize) ||

         /* finish up 2nd pass */
         USHAResult(&ctx->shaContext, digest);
}
```

8.4. The Test Driver

The following code is a main program test driver to exercise the code in sha1.c, sha224-256.c, and sha384-512.c. The test driver can also be used as a stand-alone program for generating the hashes.

See also [RFC2202], [RFC4231], and [SHAVS].

```
/************************** shatest.c ***************************/
/********************* See RFC 4634 for details ******************/
/*
 *  Description:
 *    This file will exercise the SHA code performing
 *      the three tests documented in FIPS PUB 180-2
 *        (http://csrc.nist.gov/publications/fips/
 *         fips180-2/fips180-2withchangenotice.pdf)
 *      one that calls SHAInput with an exact multiple of 512 bits
 *      the seven tests documented for each algorithm in
 *        "The Secure Hash Algorithm Validation System (SHAVS)",
 *        three of which are bit-level tests
 *        (http://csrc.nist.gov/cryptval/shs/SHAVS.pdf)
 *
 *    This file will exercise the HMAC SHA1 code performing
 *      the seven tests documented in RFCs 2202 and 4231.
 *
 *    To run the tests and just see PASSED/FAILED, use the -p option.
 *
 *    Other options exercise:
 *      hashing an arbitrary string
 *      hashing a file's contents
 *      a few error test checks
 *      printing the results in raw format
 *
 *  Portability Issues:
 *    None.
 *
 */

9. Security Considerations

This document is intended to provides the Internet community convenient access to source code that implements the United States of America Federal Information Processing Standard Secure Hash Algorithms (SHAs) [FIPS180-2] and HMACs based upon these one-way hash functions. See license in Section 1.1. No independent assertion of the security of this hash function by the authors for any particular use is intended.
